Statistical Learning, Fall 2022-23 Homework exercise 2 Due date: 15 Nov. 2022 before class

1. Population Optimizer of absolute loss

Prove that for absolute loss: $L_{abs}(Y, f(X)) = |Y - f(X)|$, EPE is minimized by setting $f^*(x) = Median(Y|X = x)$

Hint: you may find the following identity useful:

$$\int_{y>c} (y-c)dP(y) = \int_{y>c} Pr(Y>y)dy$$

(a) Generalization to quantile loss The τ th quantile loss for $0 < \tau < 1$ is defined as:

$$L_{\tau}(Y, f(X)) = \begin{cases} \tau \times (Y - f(X)) & \text{if } Y - f(X) > 0\\ -(1 - \tau) \times (Y - f(X)) & \text{otherwise} \end{cases}$$

Prove that the EPE is minimized by setting $f^*(x)$ to be the τ th quantile of P(Y|X = x), i.e., $P(Y \leq f^*(x)|X = x) = \tau$

2. ESL 2.3: Derive equation (2.24) (expected median distance to origin's nearest neighbor in an ℓ_p ball):

$$d(p,n) = (1 - \frac{1}{2}^{1/n})^{1/p}$$

Suggested approach:

- (a) Find the probability that all observations are outside a ball of radius r < 1, as a function of r.
- (b) You are looking for r such that this probability is 1/2.

Plot d(p,n) against p for $n \in \{100, 5000, 100000\}$ and $p \in \{3, 5, 10, 20, 50, 100\}$ (make one curve for every value of n — use the R functions plot() and lines()) and interpret the graph.

- 3. **ESL 2.7:** Compare classification performance of k-NN and linear regression on the zipcode¹ data, on the task of separating the digits 2 and 3. Use $k \in \{1, 3, 5, 7, 15\}$. Plot training and test error for k-NN choices and linear regression. Comment on the shape of the graph.
- 4. ESL 2.9 (second edition only) Consider a linear regression model, fit by least squares to a set of training examples $T = \{(X_1, Y_1), ..., (X_N, Y_N)\}$, drawn i.i.d from some population. Let $\hat{\beta}$ be the least

 $^{^{1}} Training: \ https://web.stanford.edu/~hastie/ElemStatLearn/datasets/zip.train.gz$

Testing: https://web.stanford.edu/~hastie/ElemStatLearn/datasets/zip.test.gz

Info: https://web.stanford.edu/~hastie/ElemStatLearn/datasets/zip.info

squares estimate. Suppose we also have some other ("test") data drawn independently from the same distribution $\{(\tilde{X}_1, \tilde{Y}_1), ..., (\tilde{X}_M, \tilde{Y}_M)\}$. Prove that:

$$\frac{1}{N}\mathbb{E}(\sum_{i=1}^{N}(Y_i - X_i^T\hat{\beta})^2) \le \frac{1}{M}\mathbb{E}(\sum_{i=1}^{M}(\tilde{Y}_i - \tilde{X}_i^T\hat{\beta})^2),$$

that is, the expected squared error in-sample is always bigger than out of sample in least squares fitting. Note that the values X are also random variables here, and the expectation is over everything that is random, including X, Y and $\hat{\beta}$.

Hint: There are several ways to prove this. One starts from considering the best possible linear model we derived in class:

$$\beta^* = (E(XX^T))^{-1}E(XY),$$

and comparing both sides to it.

Note: Students who find more than one valid way to prove the result will get a bonus grade.

* Extra credit problem: Optimality of k-NN in fixed dimension

Assume $X \sim \text{Unif}([0,1]^p)$, and $Y = f(X) + \epsilon$ with $\epsilon \sim (0,\sigma^2)$ (that is, f(x) = E(Y|X = x)). Assume f is Lipschitz: $||x_1 - x_2|| < \delta \Rightarrow |f(x_1) - f(x_2)| < c\delta$, $\forall x_1, x_2 \in [0,1]^p$. Choose any sequence k(n) such that:

$$k(n) \xrightarrow{n \to \infty} \infty k(n)/n \xrightarrow{n \to \infty} 0$$

Then:

EPE(k-NN using
$$k(n)$$
) $\stackrel{n \to \infty}{\longrightarrow} EPE(f) = \sigma^2$

(The proof does not have to be completely formal, for example you can replace a binomial with its normal approximation without proof of the relevant asymptotics).
